TITLE: Determination of pesticide residues in plant material

SOURCE: Vsesoyuznoye khimicheskoye chshchestvo. Zhurnal, v. 9, no. 5, 1964, 554-560

TOPIC: Pesticide, agriculture

Abstract: In view of the constantiv increasing use of chemical agents for plant protection, which are very toxic, the determination of pesticide residues in plant material is extremely urgent. The selection of methods of determining residues is made on the basis of the following prerequisites - the method should be as specific as possible, sufficiently sensitive, and the presence of other substances should have minimum influence on the results of the analysis.

Separation of binary azeotropic mixtures by method of
stepwise rectification at two different pressures. N. I.
Bel'kin and K. E. Novikova. Zhur. Priklad. Khim. 26,
912-20(1953). Separation of binary azeotropic mixts. can be
accomplished by the method of stepwise rectification at 2
different pressures without recourse to addn. of a 3rd com-
ponent. This is based on the dependence of compn. of
azeotropic mixt. on pressure and in principle is applicable to
any binary mixt. The economy of the method increases
with increase in difference of compn. of azeotrope with pres-
sure. Rectification may be batch or continuous. A method
for computation of a continuous rectification for min. and
max. b.-p. azeotropic system is presented. Results of ex-
ptl. work with a mixt. of water-formic acid and BuOH-
BuOAc are given. V. N. Bedarski

TITLE:

Graphical Computation Methods for Binary Azeotropic Mixtures (Graficheskiy metod rascheta binarnykh azeotropnykh smesey)

PERIODICAL:

Khimicheskaya Promyshlennost', 1958, Nr 2, pp. 38-41 (USSR)

ABSTRACT:

The advantage resulting from two-step rectifications at various pressures for the purpose of separating binary azeotropic mixtures suggests the necessity of a simple method of investigation at random pressure. Since until now no practically useful theoretical method of determination has been found the method for two pressures mentioned in the title is described. A rectangular space diagram is described in which the three parameters are represented by pressure, boiling temperature and mol-percents, the latter being put down in mol-percents as abscissa, the reciprocal value of absolute boiling temperature as ordinate, and the logarithm of pressure on the z-coordinate. The modification of these three parameters can be represented as a straight line which can be projected on a plane, and which can be used for mathematical deductions, as is shown by the au-

Card 1/3

Graphical Computation Methods for Binary Azeotropic Mixtures

64-58-2-7/16

thors. A simplified method for the determination of the two-dimensional analytical geometry is described according to which the authors investigated 30 systems. From this can be concluded that the range of pressure changes at which azeotropes form is different for various systems. The continued change of composition of the azeotropic mixture according to the change of pressure is characteristic for all systems, the ranges of change, however, being different for every system. The data of azeotropes at random pressure can be represented graphically, just as well as the pressures at which the systems become azeotropic, and the concentration ranges within which an azeotropic formation takes place. A method of approximation for the investigation according to azeotropic data with a certain function (pressure) is also mentioned. Then the dependence of the azeotropic composition and of the boiling temperature on pressure is investigated. The results computed coincided with the experimentally obtained error limits tolerable in orientation computations. There are 3 figures, 1 table and 9 references, 4 of which are Soviet.

TITLE: Effect of oxides on the properties of molybdenum

SOURCE: Fizika metallov i metallovedeniye, v. 22, no. 1, 1966, 138-140

TOPIC TAGS: molybdenum, oxide formation, brittleness, metal grain structure

ABSTRACT: Oxygen is a harmful impurity in molybdenum, inducing its embrittlement at low temperatures. However, the causes of this have not previously been elucidated. Northcott (Sb. Molibden, pod. red. A. K. Katansona, M., IIL, 1959, str. 52) claims that oxygen is present in Mo in the form of the oxide MoO_2 , but it would be more correct to assume that the composition of the oxides is not unambiguous and should be expressed by the formula $\text{Mo}_{1-x}\text{O}_y$. To investigate the behavior of molybdenum oxides during heating and cooling, an oxide close in composition to that of MoO_2 was obtained following partial reduction of the polymorphic oxide MoO_3 . The obtained powder was pressed into 10x10 mm briquets and sintered in an argon

UDC: 541.45+539.56+546.77

Card 1/3

L 09019-67
ACC NR: AP6027798

atmosphere at 1000°C for 6 hr. After this, the oxide's coefficient β of linear expansion at high temperatures (up to 800°K) was measured with the aid of dilatometers, and its phase composition before and after sintering examined by x-ray structural analysis; the roentgenograms indicated that the composition of the investigated oxide corresponds to that of Mo_2O_3 . An analysis of the temperature dependence of β (coefficient of linear expansion) showed that at from 150 to 20°C the value of β for Mo_2O_3 sharply decreases. Any further decrease in temperature, however, leads to a sharp rise in β . Considering that a similar anomaly is observed for MoO_3 , it may be assumed that this effect is characteristic of molybdenum oxides in general. These findings also serve to elucidate the effect of oxygen on the properties of Mo with decrease in temperature. The mean β for Mo varies from $5.1 \cdot 10^{-6}$ at 0°C to $5.59 \cdot 10^{-6}$ at 500°C (Teplofizicheskiye svoystva veshchestv, spravochnik pod red. N. B. Vargaftika, M., Gosenergoizdat, 1956); the β for the oxide is somewhat lower. Moreover, at <100°C the β for the oxide sharply decreases. Then the volume of inclusions of molybdenum oxides decreases at a slower rate than the volume of the surrounding metal. If an oxide particle is present within a grain, the latter is subjected to internal compressive stresses which lead to an increase in hardness and decrease in plasticity. A more harmful effect is exerted by the oxide particles when they occur in between the grains. In this case tensile stresses leading to brittle intercrystalline fracture arise at the surfaces of contact between grains. Moreover, it is known that oxides

Card 2/3

L 09019-67

ACC NR: AP6027798

in molybdenum are located chiefly along the grain boundaries. This probably is the reason why semifinished molybdenum products, with their high content of oxygen in recrystallized state, display a distinct tendency toward brittle intercrystalline fracture. Orig. art. has: 2 figures.

Title : Oscillation spectra of diphenyl and decauterodiphenyl molecules

Periodical : Izv. AN SSSR. Ser. fiz. 18/6, 669-671, Nov-Dec 1954

Abstract : The oscillation spectra of $C_{12}H_{10}$ and $C_{12}D_{10}$ and the depolarization of combined diffusion spectra were investigated and the importance of such studies for theoretical interpretation and calculation of spectra is explained. New possibilities for the derivation of deuterated arom. hydrocarbons discovered during the study of isotopic exchange reaction in liquid deutero-ammonia in the presence of potassium amide are briefly discussed. The number and possible types of oscillations of the hydrocarbon molecules are tabulated. Five USSR references (1950-1954). Tables.

TITLE: Photodissociation laser

SOURCE: Zhurnal eksperimental'noy i teoreticheskoy fiziki, v. 49, no. 5, 1965.
1408-1410

TOPIC TAGS: laser, gaseous state laser, photodissociation

ABSTRACT: The authors investigated the dependence of the oscillation threshold and the pulsed energy output of a photodissociation laser based on CH₃I or CF₃I (recently fabricated by J. V. V. Kasper and G. C. Pimental [Applied physics letters, v. 5, no. 11, 1964, p. 231]) on the pressure of the gaseous CH₃I or CF₃I. In the first series of experiments, the authors used a 50-cm-long argon-filled flash tube with a 50-μf capacitor bank (voltage 2–10 kw). A 60-cm-long quartz tube with a 7-mm inner diameter equipped with Brewster-angle windows was used as the laser tube. The flash tube and the adjacent laser tube were wrapped in aluminum foil. A confocal cavity formed by two concave gold-surfaced mirrors (radius 1 m) was used in the experiments. The output energy of the CF₃I laser pulse was observed to reach a peak at a pressure

Card 1/2

L 9497-66

ACC NR: AP6000193

of 80-100 torr. At this pressure and at a pump power of 1600 J, the average output energy of the CF₃I laser was 10⁻² J and the peak power, approximately 1 kw. Up to a pump energy of 1600 J, the output energy was a linear function of the pump energy. In another series of experiments with an elliptical lamp, dielectric coated mirrors, and an effective cell and lamp length of 250 mm, the threshold for oscillation decreased by more than a factor of two. For the CF₃I laser, the threshold reached a minimum at about 80 J at a pressure of 10-20 torr. In the case of the CH₃I laser, the threshold was at a minimum at a pressure of less than 1 torr. From the stand-point of high power output CF₃I appears to be more promising than CH₃I since higher power output is obtained at higher pressure. Orig. art. has: 3 figures. [CS]

5590. NOVIKOVA L. A. and FARBER D. A. Lab. of Physiol. and Pathol. of the Nervous System, Inst. of Neurosurg., AMN, USSR, Moscow. "Electrophysiological investigations of the relationship between the acoustical and visual analysors in the presence of a dominant focus in the cerebral cortex of the rabbit" FIZIOL. Z. 1956, 42/5 (341-350). Illus. 6 (Russian text)

Monocular exposure to flickering light produces synchronization of action currents in the retina and the contralateral occipital lobe, and development of a focus of increased excitability (dominant focus in the sense of Vedenski and Ukhtomski) in the contralateral cortical visual centre. Acoustic stimuli superimposed on the visual stimulation with flickering light increase the excitation of the dominant focus, inhibit the cortical electrical activity of the opposite side and produce finally also changes in the electro-retinogram (ERG). The effect on the ERG is explained by propagation of perielectrotomonic effects from the cortical visual centres to the retina.

COVERAGE: The present book is a collection of articles presented at the Symposium on Electrophysiology held in Kiev on 1-2 July 1961. The articles in the collection are grouped into the following sections: 1) Electrophysiology of neurons (sensory, motor, and relay neurons of the spinal cord, and neurons of the retina); 2) Induced electrical potentials of the cerebral cortex; and 3) Background rhythms of the cerebral cortex. References are given following the individual chapters. No personalities are mentioned.

TITLE: The Infrared Absorption Spectra of Monosaccharides and Polysaccharides (Infrakrasnyye spektry pogloshcheniya mono- i polisakharidov)

PERIODICAL: Zhurnal Fizicheskoy Khimii, 1958, Vol. 32, Nr 4,
pp. 894 - 903 (USSR)

ABSTRACT: As an introduction the present paper explains the possibilities of the types of hydrogen bindings in mono- and polysaccharides and mentions two basic types. It is pointed out that the investigations carried out hitherto by means of infrared spectroscopy for the purpose of determining the types of hydrogen binding by observing the position and diffusion of spectral bands of the OH-group of polysaccharides are insufficient. The present experiments deal with the investigations of mono- and polysaccharides as well as of polyatomic alcohols, with comparisons of the spectra being carried out to solve the problem of the function of the absorption spectrum of the hydroxyl

Card 1/3

The Infrared Absorption Spectra of Monosaccharides and Polysaccharides

groups on their geometrical distribution within the molecule. The measurements were carried out by means of a NIKC-11 spectrometer with a Nernst rod as source of radiation; the results obtained are shown on tables and graphically as well. Among other it was observed that in d-glucoses and d-xyloses both types of hydrogen binding are existing (I. -O-HO-H...O-H and II. -O-H...O-H). The spectrum of d-galactose shows two strong low-frequency bands 3120 and 3206 cm⁻¹ which points at the presence of a greater number of bindings of type I. In the rest of the monosaccharides, on the other hand, also characteristic phenomena were observed, the explanation of which needs detailed structural investigations. The investigations of polyatomic alcohols showed that, for instance, a difference between mannite and xylite consists of the fact that the latter has more bindings of type I. Based on the spectral analyses of polysaccharides the energies of hydrogen bindings were determined and a closer classification of the relative intensity of intermolecular interactions was carried out. The energy changed

TITLE:

The Effect of the Concentration of Acids on the Rates of the Hydrolysis of Polysaccharides. Communication 14.

PERIODICAL:

Zhurnal prikladnoy khimii, 1959, Vol 32, Nr 5, pp 1081-1085 (USSR)

ABSTRACT:

The acetal bond in low- and high-molecular compounds is resistant to the action of water. Its rupture is accelerated by catalysts, like acids, the activity of which is determined by their degree of dissociation. Zheltukhin, Korol'kov and Sharkov found that the rate of hydrolysis is proportional to the concentration of the acid [Ref 4]. The hydrolysis of cellobiose, cellulose, laminarin obtained from *Laminaria Saccharina*, and xylan prepared from straw according to Konkin's and Rogovin's method [Ref 8] is investigated here. Sulfuric acid of the concentration 15.77 - 50.98%, and hydrochloric acid of 7.04 - 22.4% were used as hydrolyzing reagents. The rate of hydrolysis of cellobiose increases faster than the concentration of the acids. A doubled concentration increase raises the hydrolysis rate 10 times, in laminarin even 15 times. A three-fold increase of the hydrochloric acid concentration increases the hydrolysis rate of xylan 40 times. The

The Effect of the Concentration of Acids on the Rate of the Hydrolysis of Poly-saccharides. Communication 14.

acidity function is a value which reflects directly and completely the changes of the hydrolysis rate. The proton or hydroxonium ion interacts with the oxygen of the acetal bond forming an unstable intermediate compound. This is decomposed by the rupture of the acetal bond. The factor which determines the reaction rate is the stability of the bond between the acetal oxygen and the first carbon atom.

Determination of flowability of metals. A. A. Presnakov and L. M. Novikova. *Litovskii Metallovedeniye* 1956, No. 10, 26-8. A known quantity of a metal is poured in a container provided with a vertical cylindrical hole that allowed to run down in a cast iron chill equipped with two multilevel gages. The time taken for the metal to flow through is held as its flowability index. With Pb, Sn, Zn, Al, and Cu, the device showed a larger flowability index at higher temps, which is attributed to a greater contamination with oxides.

Some Data on the Plasticity of Nickel and Its Alloys at Elevated Temperatures. A. A. Presnyakov and L. M. Novikova (*Izv. Akad. Nauk SSSR, Tekhnicheskaya Kemiya*, 1956, (1), 76-78; *Refer. Zhur., Met.*, 1957, (8), 279).-- (In Russian). The plasticity of Ni and some of its alloys, both as cast and worked, was studied from room temp. to 1200° C., using the reduction of area in tensile testing as the criterion of plasticity. It was found that Ni with a high C content has the greatest plasticity at temp. > 700° C. Cast sheet Ni, deoxidized with Si, C, and Mg, has the lowest plasticity in the range 600°-1000° C.; at higher temp. this difference in plasticity completely disappears. All kinds of Ni, except worked annealed Ni, have a range of reduced plasticity between 300° and 700° C. It is shown that hot working (rolling) raises the plasticity of Ni and its alloys. The smallest increase in plasticity after hot rolling is shown by pure Ni; the properties of Melschior alloy change more noticeably, and the plasticity of Morsal metal increases markedly. Plasticity in the zone of hot brittleness decreases to a smaller degree in worked alloys than in cast ones.

TITLE: Investigation of the Diffusion of Sulphur in Nickel.
(Issledovaniye diffuzii sery v nikel')

PERIODICAL: Tsvetnye Metally, 1957, No.2, pp. 73 - 76 (USSR)

ABSTRACT: Brittleness of nickel parts has been found to be associated with the presence of sulphur vapour in heat-treatment furnace atmospheres. This effect has been studied by A.K. Chertaskikh but with insufficient thoroughness, and the authors present their own experimental results in this article. These were based on metallographic investigation of various nickel specimens exposed to sulphur vapours under various conditions. The rate of diffusion of sulphur into nickel was found to depend on temperature becoming appreciable at 500°C; the rate decreases with increasing degree of preliminary deformation. A photomicrograph of deformed nickel with a sulphur-saturated surface layer is shown and graphs of thickness of sulphur-affected layer vs time and vs degree of deformation are given. Tables of temperature, annealing time and depth of diffusion and of changes in composition during annealing in sulphur vapour are given. There are 4 figures and 2 tables.

TITLE: Effect of Intermolecular Reaction on the Bromination Reaction in a Binary Benzene - Nitrobenzene System (Vliyanie mezhmolekulyarnogo vzmimodeystviya na reaktsiyu bromirovaniya v dvoynoy sisteme benzol - nitrobenzol)

PERIODICAL: Zhurnal Obshchey Khimii, 1957, vol 27, No 2, pp. 328-330 (U.S.S.R.).

ABSTRACT: The reaction of benzene bromination was investigated in nitrobenzene, bromobenzene and tetrachloromethane solutions and in the absence of solvents. The initiating effect of nitrobenzene on the bromination reaction process was established only with respect to highly polar substances. The polarization of the reagents was determined by the summary dipole moment of the molecule of the solvent. The formation of nitrobenzene solvate of benzene was considered a reversible process. The effect of nitrobenzene changed only the electron system of the benzene ring; the latter distinguishes nitrobenzene from other such highly polarizing solvents as sulfuric acid, the solution in which

Card 1/3

79-2-11/58

Effect of Intermolecular Reaction on the Bromination Reaction in a
Binary Benzene - Nitrobenzene System

is accompanied by irreversible sulfonation. The solvating nitrobenzene medium which decreases the activation energy was considered to be the most favorable for benzene bromination reactions.

In the absence of a solvent the bromination reaction is maintained by thermal excitation. The initiating effect of bromobenzene as a polar solvent was demonstrated during the bromination of benzene and the kinetic curve of bromine reaction in the bromobenzene solution was perfectly similar to the curve of the nitrobenzene solution.

"Veterinariya" Vol. 30, No. 2, pp 52-56

An early and precise method for diagnosing leptospirosis in animals is important and practical. A method was developed for diagnosing leptospirosis by means of a drop test and by a test tube macroscopic agglutination reaction with virulent strains of killed antigens.

244T21

The procedure is simple and is available to a large number of medical workers. The antigens used were specific and sterile; they preserve well for a year and produce a clearly pronounced agglutination reaction with leptospiral sera in the drop test or in the test tube macroscopic agglutination reaction.
